
Norma Une 23032 Pdf Download WORK

the patients were followed up till february 1993 where they demonstrated a good disease control with elimination of the granulomas. the patients were symptom-free and had no neurological or general complications. with these results, the use of these drugs as monotherapy should be further reevaluated as we attempt to find the best modes of treatment leprosy is a chronic, granulomatous infection caused by mycobacterium leprae. immunologic reactions are controlled by the central motor nervous system to determine the principle of clinical application of homoeopathy. a unique relationship exists between immunology and the central nervous system that governs the principle of clinical application of homoeopathy. leprosy is a chronic granulomatous disease caused by mycobacterium leprae. a unique relationship exists between immunology and the central motor nervous system that governs the principle of clinical application in homoeopathy. the immune system is not confined to single site in the body : rather governed by central motor nervous system, immunocytes and their secreted molecules traffic within and among lymphoid organs and various body compartments. hence a highly complex system of communication has developed among the various cell types in the immune system. endemic leprosy is in nepal. there is no information regarding the bacillary load in different age groups. we have studied the bacillary load in different age groups and their localisation according to ridley's and julliet's classification. these were estimated by slit-skin smear and culture. a total of 143 slit-skin smears and 102 culture isolates were analysed. the mean age of patients in tuberculoid leprosy (n=78) was 30.11 +/-6.73 years. with regard to the reactional episodes (n=64), the highest (23.46%) frequency was in the age group, 15-29 years. the difference in the frequency of the reactional episodes between the male and female patients was statistically insignificant ($p>0.05$). all the isolates showed a positive reaction for m-anti-bcg, m-anti-ppd and ridley's antigens. the percentage positivity for m-anti-ppd was 84.57% and for ridley's antigens 83.08%. in cases of non-reactive leprosy, the percentage positivity for ridley's antigens was 66.67%, and for m-anti-ppd was 60.64%. most of the positive reactions were positive in both the healthy and tuberculoid leprosy groups, and between the two groups there was no significant difference ($p>0$). among the disease groups, the highest percentage positivity was in the paucibacillary group (61.10%). in the multibacillary group, there was no statistically significant difference between the positive and negative results ($p>0.05$) in conclusion, there is a high percentage of positive results with the three leprosy serological tests in healthy individuals and leprosy patients. the immunological reactions observed were not associated with the age of the subjects or with their sex.
