Another interesting new feature in this version is the File Operations panel — also known as the File Panel. A file panel is a special panel that shows thumbnail-sized versions of files and directories, which have been identified as potentially useful. So, while working, if you add a file, you will see a related thumbnail preview displayed at the bottom of the file. At that time, you can easily move your mouse over the preview image and select it to upload the file to a location of your choice. However, there is a missing feature. The preview image can't be dragged and dropped to the desktop. The thumbnail must be permanently stored. But The file operations isn't a real file manager, because it doesn't provide a feature where you can move files from one location to another. But, thank you for highlighting that! I think it will be the most useful feature in the tool. Also, this version of Photoshop is the first to use PNG8. (Adobe is talking about getting rid of the obsolete 24-bit JPEG format in the future releases of their products.) According to Adobe, the purpose of PNG8 is that the format is small in size, and the quality is not lower than JPEG 8. Therefore, it's said to be better than JPEG even though there are some disadvantages. Adobe says PNG8 is a kind of option for developing web-based applications, especially when you need to load a lot of images fast. This book is a guide for the advanced user of Photoshop who doesn't just want to create simple 3D objects, but want to sculpt and design 3D images or objects.

Photoshop uses the concept of layers. While a single image is generally worked on with a single layer, individual layers can be turned on and off to assemble an image. To inspect the exact order of a layer, hold down Alt and click on the layer thumbnail in the Layers Panel. Animations are built by combining multiple layers into one. Prior to the advent of smart objects, you were limited to moving or deleting individual layers in order to create a transition effect between them. Photoshop 7.0 allows layers to be smart objects and you can move the image many times without the layers moving with it. Select Layer > Flatten Image. This will merge all of the layers into one image that may be moved, rotated, sized, and so on. I'm working with a 3d mesh in OpenGL and I want to be able to remove all duplicate vertices/faces at runtime. I have a floating point mesh, with an array of vertices (and floating point arrays for the normal and texcoords). The vertices are packed and tightly bound. I have an array of indices too, but I'm not sure if this is relevant to the problem. I have thought about packing this mesh into a C/C++ array, sorting the array (by updating the indices) and removing all duplicates. This would be OK if there is no more than a few duplicate vertices, but I'm dealing with some meshes with over 30k vertices! Does anyone know of a more efficient way to do this? I could resort to a custom CPU function, or even packing the mesh into a binary data file and sorting by indices. But these ideas are also rather intensive and I'm not sure what you might do if the new mesh has a different topology, so I'm looking for some better ideas. Thanks! A: Are vertices tightly bound? If that's the case, I'm sure you can cast away the index buffer and instead keep off-screen buffers that are updated on-the-fly. As far as I know, there's no speed or memory problems with any of this. You can even do performance and memory improvements by just caching a vertex cache for the sake of rendering and loading the cache. If vertices are not tightly bound, then you may be able to use a sphere box filter to cheapen triangles. You compute uv coordinates and then for each triangle, check for any other triangles that have the same uv coordinates. If there are none, the triangle can be used. If there are multiple, discard one. Another trick is to use a hash tree and search for an object based on hash values to learn if there are duplicates. The most effective solution is to unfreeze all vertices and use a second iterative algorithm to free all duplicate vertices. If you're not using the index buffer, then you'll have to sort your mesh based on vertex value to discover duplicates. A: In my experience, the best way to do this is by using a Hash-Table. This is a memory-efficient way to determine if two vertices are identical by storing a 64-bit hash of the vertices in an array. Each collision represents a vertex duplicate. If the array becomes full, it is rebalanced by deleting the least recently added vertex and re-inserting it at the top of the array.
